Chapter 3: Linear Regression

Linear regression is a simple approach for supervised learning when the response is quantitative. Linear regression has a long history and we could actually spend most of this semester talking about it.

Although linear regression is not the newest, shiniest thing out there, it is still a highly used technique out in the real world. It is also useful for talking about more modern techniques that are **generalizations** of it.

Aidge regression, Lasso, logistic regression, GAMs.

We will review some key ideas underlying linear regression and discuss the <u>least squares</u> approach that is most commonly used to fit this model.

Linear regression can help us to answer the following questions about our Advertising data:

- 1. Is there a relationship by advertising and sales?
 i.e. should people spend money on ads?
- à. How strong is that relationship? i.e. how well conve predict sales based on ad budjets?
- 3. Which media contribute to sales?
- 4. How accurately can we predict the effect of each medium on sales?
- 5. How accurately con we predict future sales?
- 6. Is the relationship linear?
- 7. Is there synergy among the ad media?
 i.e. is \$50k for TV and \$50k for radio "better" for sales than
 \$160k on radio or TV alone?

1 Simple Linear Regression

Simple Linear Regression is an approach for prediction a quantitative response Y on the basis of a single predictor variable X.

It assumes:

- approximately linear relationship between X and Y
- random error term is Normally distributed
- handom error term has constant variance

Which leads to the following model:

$$y = \beta_0 + \beta_1 X + \xi$$

$$\xi \sim N(0, 6^2)$$
assumptions about error

For example, we may be interested in regressing sales onto TV by fitting the model

sales =
$$\beta_0$$
 + β_1 xTV + ϵ

whenour constants (intrapt ϵ slope).

("parameters" or "molel coefficients").

ed training data to produce estimates $\hat{\beta}_0$ and $\hat{\beta}_1$, we can predict

Once we have used training data to produce estimates $\hat{\beta}_0$ and $\hat{\beta}_1$, we can predict future sales on the basis of a particular TV advertising budget.

1.1 Estimating the Coefficients

In practice, β_0 and β_1 are **unknown**, so before we can predict \hat{y} , we must use our training data to estimate them.

2

Let $(x_1,y_1),\ldots,(x_n,y_n)$ represent n observation pairs, each of which consists of a measurement of X and Y.

n= 200 observations

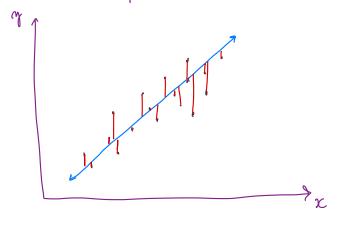

Goal: Obtain coefficient estimates $\hat{\beta}_0$ and $\hat{\beta}_1$ such that the linear model fits the available data well.

We want to find intercept $\hat{\beta}_0$ and slope $\hat{\beta}_1$, s.f. resulting line is "close" to n=200 points. The most common approach involves minimizing the least squares criterion.

Let
$$\hat{y}_i = \hat{\beta}_0 + \hat{\beta}_i x_i$$
 prediction for y based on its value $q \times e_i = y_i - \hat{y}_i$: its "residual"

$$RSS = e_1^2 + ... + e_n^2$$
 residuel sum of squeres

choose
$$\hat{\beta}_{o}$$
 and $\hat{\beta}_{i}$ to minimize RSS.

The least squares approach results in the following estimates:

es approach results in the following estimates:

$$\hat{\beta}_{1} = \frac{\hat{\Sigma}(x; -\bar{x})(\eta; -\bar{\eta})}{\hat{\Sigma}(x; -\bar{x})^{2}}$$

$$\hat{\beta}_{0} = \bar{\eta} - \hat{\beta}_{1}\bar{x}$$
Use calculus \rightarrow take derivatives

set to 0, solve for $\hat{\beta}_{1}$ and $\hat{\beta}_{2}$.

$$\hat{\beta}_{1} = \frac{\hat{\Sigma}(x; -\bar{x})(\eta; -\bar{\eta})}{\hat{\Sigma}(x; -\bar{x})^{2}}$$
Use calculus \rightarrow take derivatives

$$\hat{\beta}_{1} = \frac{\hat{\Sigma}(x; -\bar{x})(\eta; -\bar{\eta})}{\hat{\Sigma}(x; -\bar{x})^{2}}$$
Use calculus \rightarrow take derivatives

$$\hat{\beta}_{1} = \frac{\hat{\Sigma}(x; -\bar{x})(\eta; -\bar{\eta})}{\hat{\Sigma}(x; -\bar{x})^{2}}$$
Use calculus \rightarrow take $\hat{\beta}_{2}$ and $\hat{\beta}_{3}$ and $\hat{\beta}_{4}$ are $\hat{\beta}_{3}$ and $\hat{\beta}_{4}$ are $\hat{\beta}_{4}$ are $\hat{\beta}_{4}$ and $\hat{\beta}_{4}$ are $\hat{\beta$

We can get these estimates using the following commands in R and tidymodels:

```
library(tidymodels) ## load library
   ## load the data in
   ads <- read_csv("../data/Advertising.csv", col_select = -1)</pre>
   ## fit the model
     set_mode("regression") |>

1.2 Assessing Accuracy

Recall we assume the true relationship between X and Y takes the form

funknown, & mean-zero random error

If f is to be approximated by a linear function, we can write this relationship as

y = fo + fix + E catch all term for what he miss w/ this module other relationship & may not be linear, may be other variables that cause variation in y, measurement error.

and when we fit the model to the training data, we get the following estimate of the population model

least line. $Y = \hat{\beta}_0 + \hat{\beta}_1 X$

But how close this this to the truth? weasure u/ standard error.

 $\sqrt{\operatorname{Var}(\hat{\beta}_{0})} = \operatorname{SE}(\hat{\beta}_{0}) = \sqrt{6^{2} \left[\frac{1}{n} + \frac{\bar{x}^{2}}{\hat{\Sigma}(x_{1} - \bar{x})^{2}} \right]}$ $\sqrt{\operatorname{Var}(\hat{\beta}_{i})} = \operatorname{SE}(\hat{\beta}_{i}) = \sqrt{\frac{\hat{g}^{2}}{\hat{\Sigma}(\infty; -\bar{\Sigma})^{2}}}$

In general, (σ^2) is not known, so we estimate it with the *residual standard error*,

We can use these standard errors to compute confidence intervals and perform hypothesis tests.

95% CI for
$$\beta_i$$
: $\hat{\beta}_i + 2\hat{SE}(\hat{\beta}_i)$
95% CI for β_i : $\hat{\beta}_i + 2\hat{SE}(\hat{\beta}_i)$

Hypothesis Test: Ho: There is no relation ship both/ X and Y

Ho: \$1 = 0

Ho: \$1 = 0

Ho: \$1 = 0 Ha: There is a Cliner) relationship both X and Y

?: is \(\beta\), for enough away from 0 to be confident it is not zero? How for is enough? depends on SE(\beta\))

 $t = \frac{\hat{\beta}_1 - 0}{\hat{SE}(\hat{\beta}_1)} \sim t_{n-2} \implies \frac{\text{conpute } P(\text{observiny any number equal to ItI on larger}) = p\text{-value.}}{\text{Small } p\text{-value nears highly unlikely to see this } t \text{ given}}$ $\text{Ho} \implies \text{reject Ho}!$

Once we have decided that there is a significant linear relationship between X and Y that is captured by our model, it is natural to ask

To what extent does the model fit the data?

The quality of the fit is usually measured by the *residual standard error* and the \mathbb{R}^2 statistic.

RSE: Roughly speaking, the RSE is the average amount that the response will deviate from the true regression line. This is considered a measure of the *lack of fit* of the model to the data.

 R^2 : The RSE provides an absolute measure of lack of fit, but is measured in the units of Y. So, we don't know what a "good" RSE value is! R^2 gives the proportion of variation in Y explained by the model.

2 Multiple Linear Regression

Simple linear regression is useful for predicting a response based on one predictor variable, but we often have **more than one** predictor.

How can we extend our approach to accommodate additional predictors?

We can give each predictor a separate slope coefficient in a single model.

We interpret β_j as the "average effect on Y of a one unit increase in X_j , holding all other predictors fixed".

In our Advertising example,

2.1 Estimating the Coefficients

As with the case of simple linear regression, the coefficients $\beta_0, \beta_1, \ldots, \beta_p$ are unknown and must be estimated. Given estimates $\hat{\beta}_0, \hat{\beta}_1, \ldots, \hat{\beta}_p$, we can make predictions using the formula

The parameters are again estimated using the same least squares approach that we saw in the context of simple linear regression.

```

2.2 Some Important Questions

When we perform multiple linear regression we are usually interested in answering a few important questions:

1.

2.

3.

4.

2.2.1 Is there a relationship between response and predictors?

We need to ask whether all of the regression coefficients are zero, which leads to the following hypothesis test.

 H_0 :

 H_a :

This hypothesis test is performed by computing the *F*-statistic

F =

2.2.2 Deciding on Important Variables

After we have computed the F-statistic and concluded that there is a relationship between predictor and response, it is natural to wonder

Which predictors are related to the response?

We could look at the p-values on the individual coefficients, but if we have many variables this can lead to false discoveries.

Instead we could consider variable selection. We will revisit this in Ch. 6.

2.2.3 Model Fit

Two of the most common measures of model fit are the RSE and R^2 . These quantities are computed and interpreted in the same way as for simple linear regression.

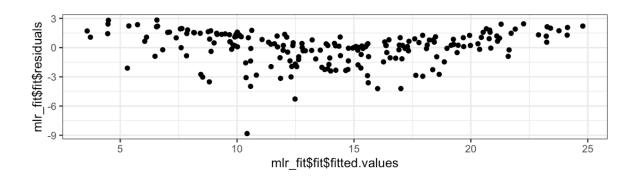

Be careful with using these alone, because R^2 will **always increase** as more variables are added to the model, even if it's just a small increase.

```

```

It may also be useful to plot residuals to get a sense of the model fit.

```
ggplot() +
  geom_point(aes(mlr_fit$fit$fitted.values, mlr_fit$fit$residuals))
```

3 Other Considerations

3.1 Categorical Predictors

So far we have assumed all variables in our linear model are quantitiative.

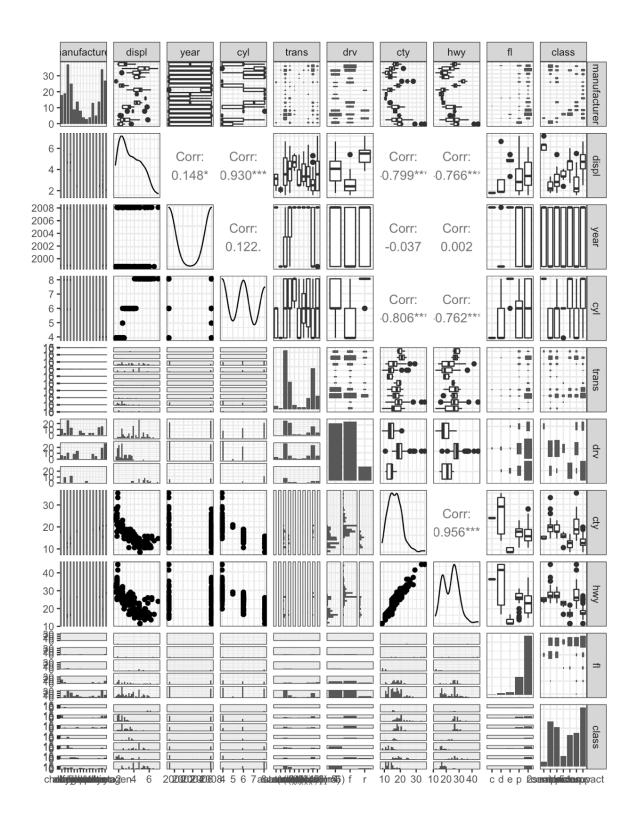

For example, consider building a model to predict highway gas mileage from the mpg data set.

head(mpg)

```
## # A tibble: 6 × 11

```

```
library(GGally)

mpg %>%
  select(-model) %>% # too many models
  ggpairs() # plot matrix
```

To incorporate these categorical variables into the model, we will need to introduce k-1 dummy variables, where k= the number of levels in the variable, for each qualitative variable.

For example, for drv, we have 3 levels: 4, f, and r.

```

3.2 Extensions of the Model

The standard regression model provides interpretable results and works well in many problems. However it makes some very strong assumptions that may not always be reasonable.

Additive Assumption

The additive assumption assumes that the effect of each predictor on the response is not affected by the value of the other predictors. What if we think the effect should depend on the value of another predictor?

```
lm spec |>
 fit(sales ~ TV + radio + TV*radio, data = ads) |>
 pluck("fit") |>
 summary()
##
## Call:
## stats::lm(formula = sales ~ TV + radio + TV * radio, data = data)
##
## Residuals:
##
      Min
               10 Median
                              3Q
                                     Max
## -6.3366 -0.4028 0.1831 0.5948 1.5246

## TV
             1.910e-02 1.504e-03 12.699
                                            <2e-16 ***
## radio
              2.886e-02 8.905e-03
                                  3.241
                                            0.0014 **
## TV:radio
           1.086e-03 5.242e-05 20.727
                                            <2e-16 ***
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 0.9435 on 196 degrees of freedom
## Multiple R-squared: 0.9678, Adjusted R-squared: 0.9673
## F-statistic: 1963 on 3 and 196 DF, p-value: < 2.2e-16
```

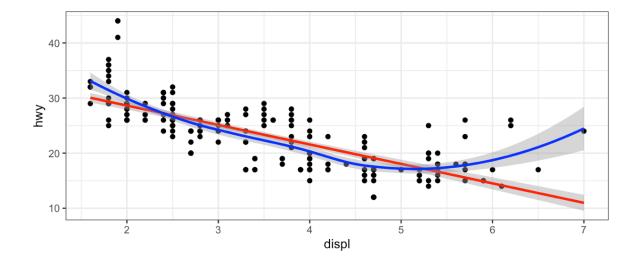

Alternatively:

```
rec_spec_interact <- recipe(sales ~ TV + radio, data = ads) |>
  step_interact(~ TV:radio)
lm_wf_interact <- workflow() |>
  add_model(lm_spec) |>
  add_recipe(rec_spec_interact)
lm_wf_interact |> fit(ads)
## == Workflow [trained]
## Preprocessor: Recipe
## Model: linear_reg()
##
## — Preprocessor
## 1 Recipe Step
##
## • step_interact()
##
## — Model
##
## Call:
## stats::lm(formula = ..y ~ ., data = data)
## Coefficients:
                        TV
## (Intercept)
                                  radio
                                          TV x radio
##
     6.750220 0.019101 0.028860
                                            0.001086
```

Linearity Assumption

The linear regression model assumes a linear relationship between response and predictors. In some cases, the true relationship may be non-linear.

```
ggplot(data = mpg, aes(displ, hwy)) +
  geom_point() +
  geom_smooth(method = "lm", colour = "red") +
  geom_smooth(method = "loess", colour = "blue")
```

```
lm spec |>
  fit(hwy ~ displ + I(displ^2), data = mpg) |>
 pluck("fit") |> summary()
##
## Call:
## stats::lm(formula = hwy ~ displ + I(displ^2), data = data)
##
## Residuals:
      Min
               1Q Median 3Q
                                        Max
## -6.6258 -2.1700 -0.7099 2.1768 13.1449
## Coefficients:
              Estimate Std. Error t value Pr(>|t|)
## (Intercept) 49.2450 1.8576 26.510 < 2e-16 ***
## displ -11.7602 1.0729 -10.961 < 2e-16 ***
## I(displ^2) 1.0954 0.1409 7.773 2.51e-13 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 3.423 on 231 degrees of freedom
## Multiple R-squared: 0.6725, Adjusted R-squared: 0.6696
## F-statistic: 237.1 on 2 and 231 DF, p-value: < 2.2e-16
```

3.3 Potential Problems

- 1. Non-linearity of response-predictor relationships
- 2. Correlation of error terms
- 3. Non-constant variance of error terms
- 4. Outliers

4 K-Nearest Neighbors

In Ch. 2 we discuss the differences between *parametric* and *nonparametric* methods. Linear regression is a parametric method because it assumes a linear functional form for f(X).

A simple and well-known non-parametric method for regression is called K-nearest neighbors regression (KNN regression).

Given a value for K and a prediction point x_0 , KNN regression first identifies the K training observations that are closest to x_0 (\mathcal{N}_0). It then estimates $f(x_0)$ using the average of all the training responses in \mathcal{N}_0 ,

```
set.seed(445) #reproducibility
## generate data
x <- rnorm(100, 4, 1) # pick some x values
y < -0.5 + x + 2*x^2 + rnorm(100, 0, 2) # true relationship
df \leftarrow data.frame(x = x, y = y) # data frame of training data
knn spec <- nearest neighbor(mode = "regression")</pre>
for (k in seq(2, 10, by = 2)) {
  knn spec |>
    fit(y ~ x, data = df, neighbors = k) |>
    augment(new data = df) |>
    ggplot() +
    geom point(aes(x, y)) +
    geom_line(aes(x, .pred), colour = "red") +
    ggtitle(paste("KNN, k = ", k)) +
    theme(text = element_text(size = 30)) -> p
 print(p)
}
lm_spec |>
  fit(y \sim x, df) >
  augment(new_data = df) |>
  ggplot() +
    geom\ point(aes(x, y)) +
```

```
geom_line(aes(x, .pred), colour = "red") +
ggtitle("Simple Linear Regression") +
theme(text = element_text(size = 30)) # slr plot
```
